

Milestone 3

Hash Comparison

Added logic to compare each new hash against the previous one for the same agent. The backend walks the stored records in chronological order and flags any directory whose hash value changed between consecutive snapshots. This comparison result is returned to the frontend alongside the hash data.

The hash records table was also restructured to store results per agent, allowing the backend to track multiple monitored machines independently.

Alerts

The frontend uses the comparison result to highlight changed directories in the hash history view. An alert panel was added to surface any changes detected within the last 24 hours across all agents. Agents with active alerts are visually distinguished in the agent list.

Login

Access to the web UI was restricted behind a login page. The backend validates credentials against environment variables and issues a server-side session. All data endpoints require a valid session. Sessions expire after 24 hours of inactivity and are cleaned up automatically.
