

# Milestone 5

## Per-File Hashing

Previous milestones hashed each watched directory as a single SHA-256 value. This detected when something changed but not which file was responsible. The agent now computes an individual SHA-256 hash for every file and stores results as a map of file path to hash value. The existing JSONB schema and change detection logic required no changes.

A configurable file size threshold was added to skip large files such as media. The default is 100 MB and is adjustable per-agent from the web UI.

## Timeline View

The frontend detail view was redesigned as a timeline. Rows with changes expand to list individual files within watched directories, each labeled as added, modified or deleted.

Any record can be set as the new baseline. Future comparisons start from that record, allowing the user to acknowledge a known state and track only subsequent changes.

## Alert Management

Alerts are displayed in a dedicated panel and can be dismissed individually without affecting the underlying history.

## Automated Testing

Unit and integration tests were written for the agent and backend, with a GitHub Actions workflow running on every push. The Go tests cover skip path matching, hash correctness, large file filtering and change detection. The Python tests cover the change detection algorithm and all API endpoints against a real PostgreSQL database.

The CI workflow runs both jobs in parallel. The backend job provisions a PostgreSQL container using GitHub Actions' services block, keeping the test database separate from the production Supabase instance.
